Advanced Time Series Forecasting, Optimization and Explainability

Course: Advanced Topics in Deep Learning — 2nd Semester 2025/2026

Dataset: Jena Climate (Weather) — Air Temperature Forecasting

Task: Multivariate-input, univariate-output, multi-step forecasting

---

10. Efficiency & Resource Analysis
11. Comparative Analysis & Discussion
12. Conclusion

1. Setup & Imports

Install and import all required libraries. Set random seeds for reproducibility.

In [80]:
```
# !pip install -r "requirements.txt"
```

In [81]:
```
# 1. Standard Library & Utilities
import os
import time
import random
import urllib.request
import zipfile
```

```python
import warnings
warnings.filterwarnings('ignore')

# 2. Core Data Science
import numpy as np
import pandas as pd

# 3. Data Visualization
import matplotlib.pyplot as plt
import seaborn as sns
import plotly.express as px
import plotly.graph_objects as go

# 4. Machine Learning & Metrics
from sklearn.preprocessing import MinMaxScaler, StandardScaler
from sklearn.metrics import mean_squared_error, mean_absolute_error, r2_score

# 5. Deep Learning (PyTorch)
import torch
import torch.nn as nn
from torch.utils.data import Dataset, DataLoader

# 6. Explainable AI (XAI)
import shap
from lime import lime_tabular

# 7. Evolutionary Algorithms & Optimization
from deap import base, creator, tools, algorithms  # DEAP framework
# import optuna  # Alternative: Optuna with evolutionary sampler
```

In [82]:

```python
#  Reproducibility
SEED = 33 # 33 RULES THE WORLD. Note: For the curious, the 33 is a number that happ
# Second Note: for some tests in the next steps we utilize other seeds so that we c
def set_seed(seed=SEED):
    """Set random seeds for reproducibility."""
    np.random.seed(seed)
    torch.manual_seed(seed)
    if torch.cuda.is_available():
        torch.cuda.manual_seed_all(seed)
    torch.backends.cudnn.deterministic = True
    torch.backends.cudnn.benchmark = False

set_seed()

#  Device Configuration
DEVICE = torch.device('cuda' if torch.cuda.is_available() else 'cpu') #if you have
print(f"Using device: {DEVICE}")
if torch.cuda.is_available():
    print(f"GPU: {torch.cuda.get_device_name(0)}")
```

```
Using device: cuda
GPU: NVIDIA GeForce RTX 4050 Laptop GPU
```

2. Data Loading

Load the Jena Climate dataset. Keep only the **required variables**:

- `Date Time` — timestamp
- `T (degC)` — air temperature (**TARGET**)
- `p (mbar)` — atmospheric pressure
- `rh (%)` — relative humidity
- `wv (m/s)` — wind speed
- `max. wv (m/s)` — maximum wind speed
- `wd (deg)` — wind direction

In [83]:
```
DATA_URL = "https://storage.googleapis.com/tensorflow/tf-keras-datasets/jena_climat
DATA_DIR = "data/"
DATA_FILE = os.path.join(DATA_DIR, "jena_climate_2009_2016.csv")

#if the code doenst work for click on the url and download the file manually, then
# The code will check if the file exists before attempting to download it, so you w
if not os.path.exists(DATA_FILE):
    os.makedirs(DATA_DIR, exist_ok=True)
    zip_path = os.path.join(DATA_DIR, "jena_climate_2009_2016.csv.zip") # Temporary
    print("Downloading Jena Climate dataset")
    urllib.request.urlretrieve(DATA_URL, zip_path)
    print("Extracting...")
    with zipfile.ZipFile(zip_path, 'r') as z:
        z.extractall(DATA_DIR)
    os.remove(zip_path)
    print("Done")
else:
    print("Dataset already exists, skipping download.")

df_raw = pd.read_csv(DATA_FILE)
print(f"Raw dataset shape: {df_raw.shape}")
df_raw.head()
```

```
Dataset already exists, skipping download.
Raw dataset shape: (420551, 15)
```

3. Exploratory Data Analysis

Understand the structure and patterns in the data before modelling. Here are some key EDA steps we will perform:

- **Full time series plot**: Visualize the entire temperature time series to identify overall trends and seasonality.
- **Zoomed-in view**: Focus on a specific month to see finer details and short-term patterns.
- **Correlation analysis**: Analyze correlations between the target variable and other features to identify potential predictors.

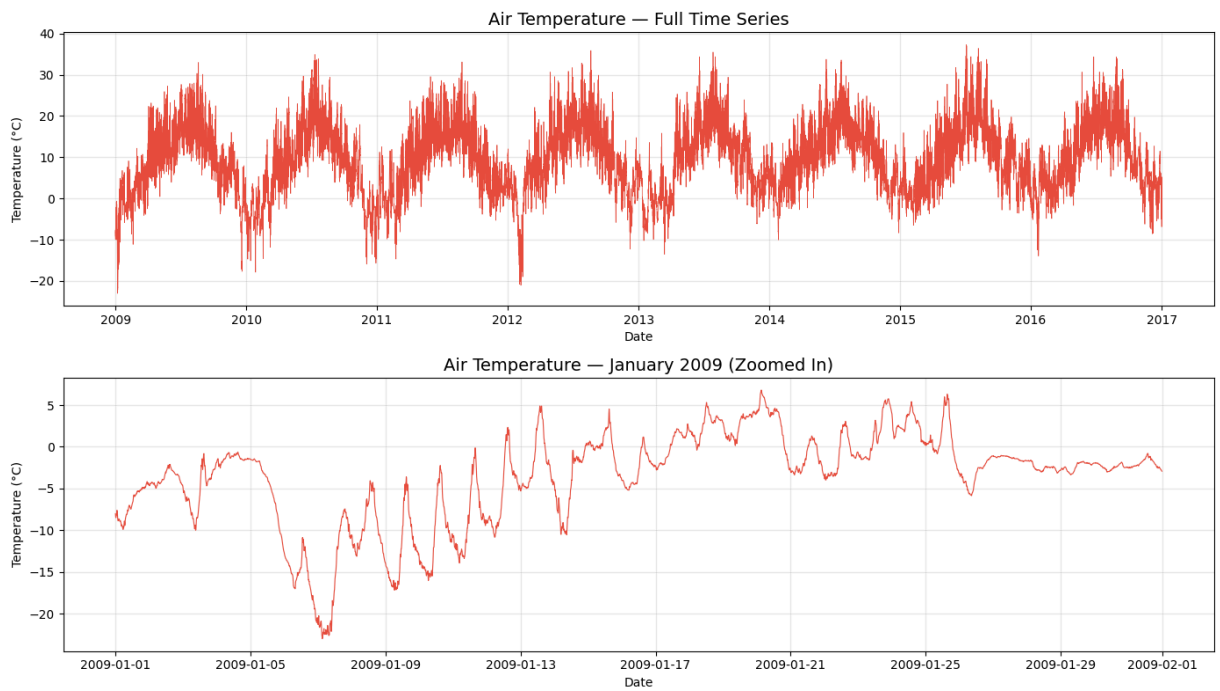
In [85]:
```
#  Full time series plot
fig, axes = plt.subplots(2, 1, figsize=(14, 8))

axes[0].plot(df.index, df['T (degC)'], linewidth=0.5, color='#e74c3c')
axes[0].set_title('Air Temperature — Full Time Series', fontsize=14)
axes[0].set_ylabel('Temperature (°C)')
axes[0].set_xlabel('Date')
axes[0].grid(True, alpha=0.3)

#  Zoomed-in view: first month
one_month = df.loc['2009-01-01':'2009-01-31']
axes[1].plot(one_month.index, one_month['T (degC)'], linewidth=0.8, color='#e74c3c'
axes[1].set_title('Air Temperature — January 2009 (Zoomed In)', fontsize=14)
axes[1].set_ylabel('Temperature (°C)')
axes[1].set_xlabel('Date')
axes[1].grid(True, alpha=0.3)

plt.tight_layout()
plt.show()

# Comments:
# - Clear yearly seasonality (warm summers, cold winters)
# - Daily patterns visible in the zoomed view (warmer during the day, cooler at nig
# - Some noise/short-term fluctuations present, typical of weather data
```



In [86]:
```
# Plot all input variables as subplots
feature_cols = ['T (degC)', 'p (mbar)', 'rh (%)', 'wv (m/s)', 'max. wv (m/s)', 'wd
colors = ['#e74c3c', '#3498db', '#2ecc71', '#f39c12', '#9b59b6', '#1abc9c']

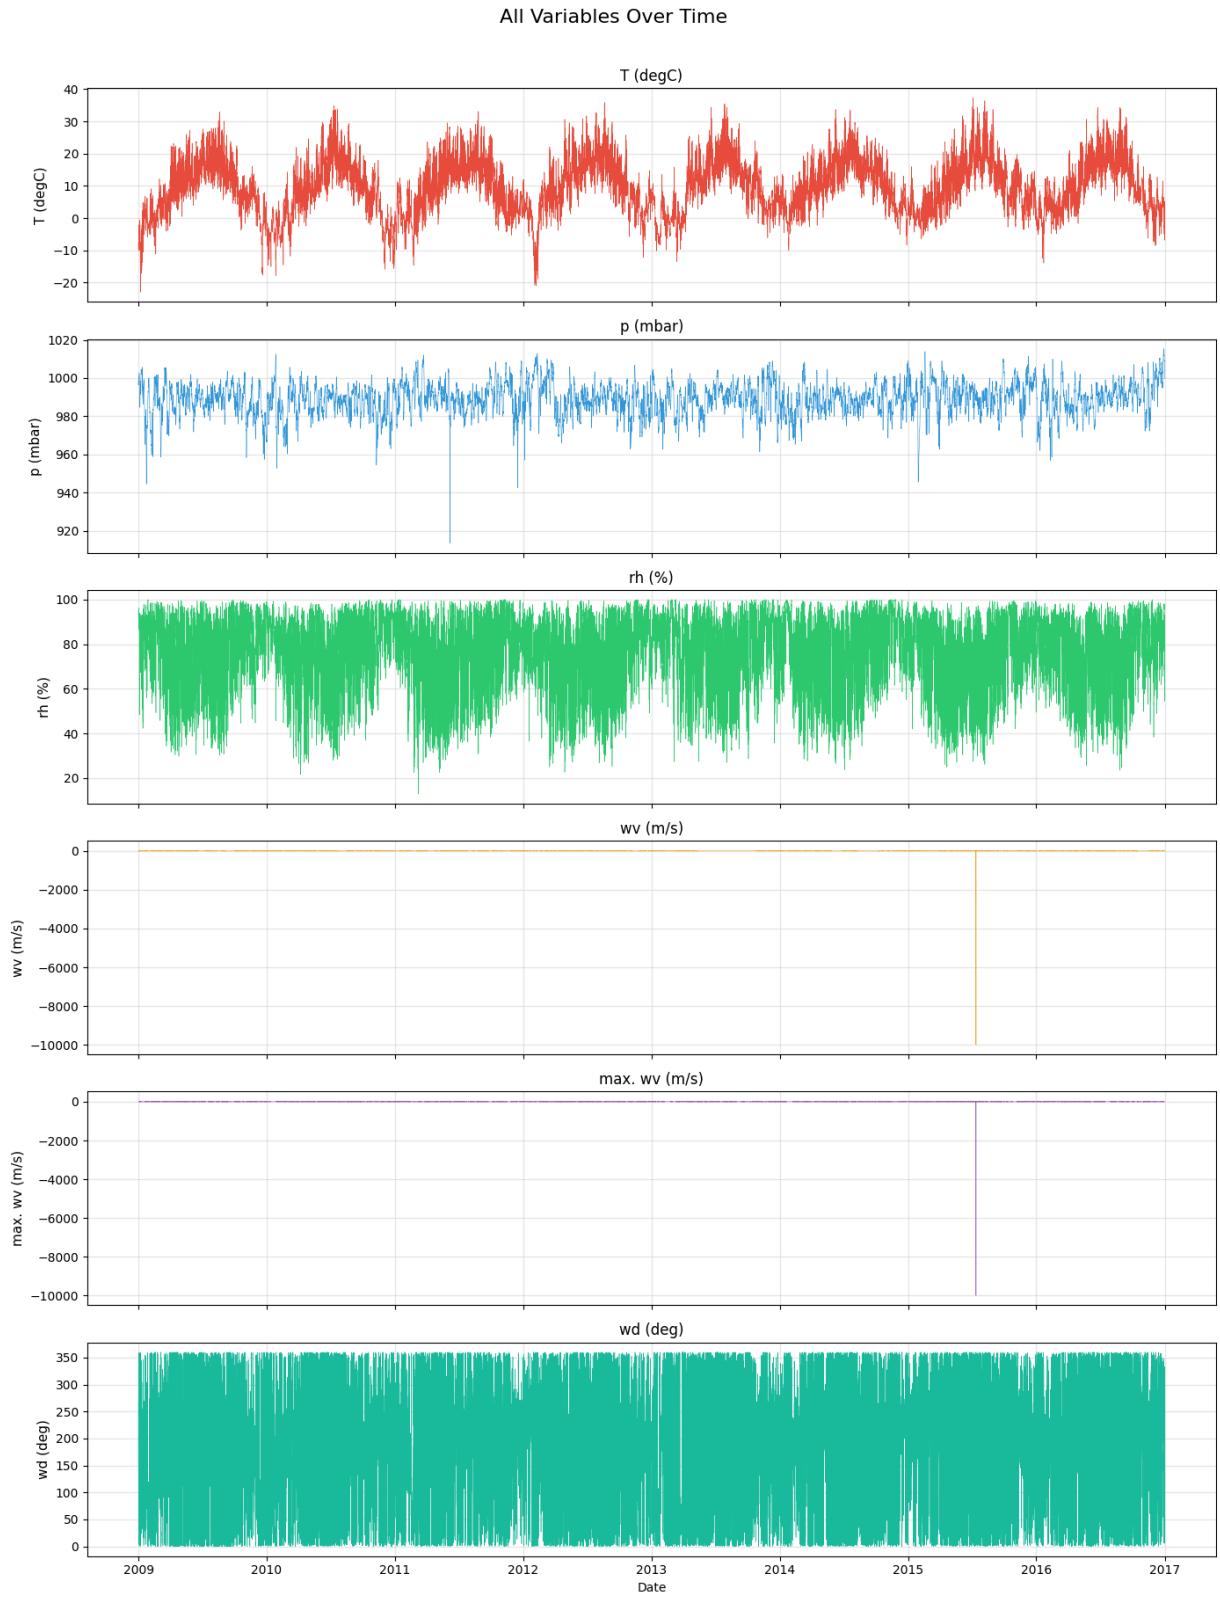
fig, axes = plt.subplots(len(feature_cols), 1, figsize=(14, 3 * len(feature_cols)),

for i, (col, color) in enumerate(zip(feature_cols, colors)):
    axes[i].plot(df.index, df[col], linewidth=0.4, color=color)
    axes[i].set_ylabel(col, fontsize=11)
```

```
    axes[i].grid(True, alpha=0.3)
    axes[i].set_title(col, fontsize=12)

axes[-1].set_xlabel('Date')
fig.suptitle('All Variables Over Time', fontsize=16, y=1.01)
plt.tight_layout()
plt.show()

# Observations:
# - Temperature and humidity show clear seasonal patterns
# - Pressure is relatively stable with some short-term weather events
# - Wind speed has sporadic spikes (potential outliers)
# - Wind direction spans 0-360° as expected
```



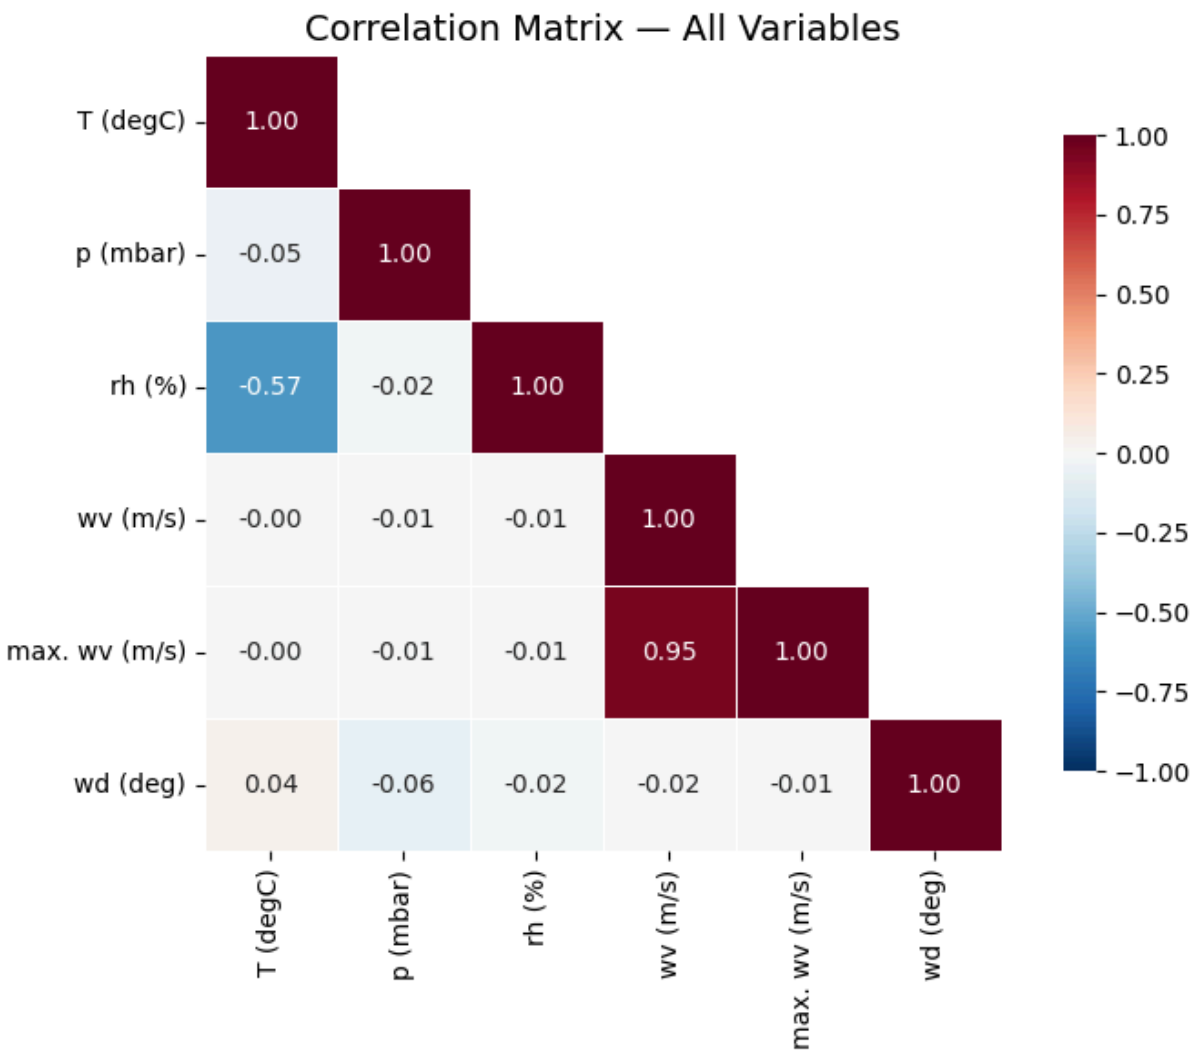
In [87]:
```
# Compute correlation matrix
corr_matrix = df.corr()

# Plot heatmap
fig, ax = plt.subplots(figsize=(8, 6))
mask = np.triu(np.ones_like(corr_matrix, dtype=bool), k=1)
sns.heatmap(corr_matrix, annot=True, fmt='.2f', cmap='RdBu_r', center=0,
            mask=mask, square=True, linewidths=0.5, ax=ax,
```

```
            vmin=-1, vmax=1, cbar_kws={'shrink': 0.8})
ax.set_title('Correlation Matrix — All Variables', fontsize=14)
plt.tight_layout()
plt.show()

# Identify correlations with temperature
print("Correlations with Temperature T (degC):")
print(corr_matrix['T (degC)'].drop('T (degC)').sort_values(ascending=False).to_stri

# Discussion:
# - Relative humidity (rh) typically has a strong negative correlation with tempera
# - Pressure may show weak-to-moderate correlation
# - Wind variables tend to be less correlated with temperature
# - Highly correlated features may provide redundant information
```



```
Correlations with Temperature T (degC):
wd (deg)          0.038732
max. wv (m/s)    -0.002871
wv (m/s)         -0.004689
p (mbar)         -0.045375
rh (%)           -0.572416
```

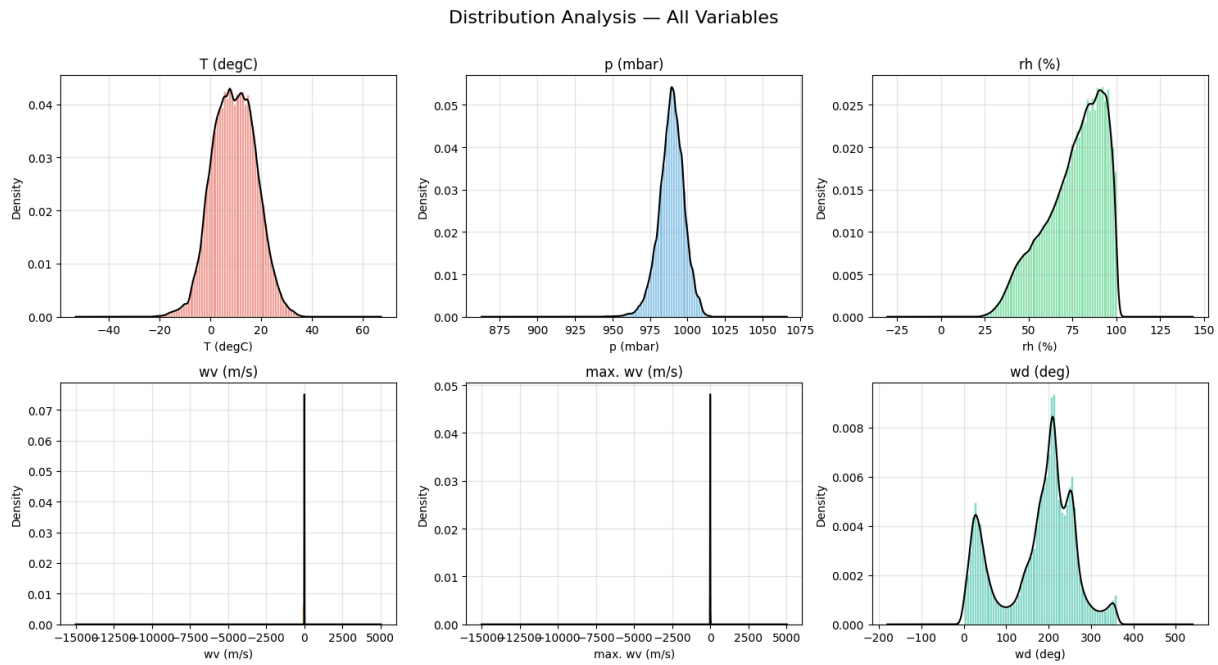
In [88]:

```
# Histograms + KDE for each variable
fig, axes = plt.subplots(2, 3, figsize=(15, 8))
axes = axes.flatten()
```

```
for i, col in enumerate(feature_cols):
    axes[i].hist(df[col].dropna(), bins=60, density=True, alpha=0.6, color=colors[i
    df[col].dropna().plot.kde(ax=axes[i], color='black', linewidth=1.5)
    axes[i].set_title(col, fontsize=12)
    axes[i].set_xlabel(col)
    axes[i].set_ylabel('Density')
    axes[i].grid(True, alpha=0.3)

fig.suptitle('Distribution Analysis — All Variables', fontsize=16, y=1.01)
plt.tight_layout()
plt.show()

# Observations:
# - Temperature: roughly bimodal (summer vs winter), slight negative skew
# - Pressure: approximately normal, centered around ~990 mbar
# - Humidity: left-skewed, often high values
# - Wind speed: right-skewed with some outliers at high values
# - Wind direction: multimodal (prevailing wind directions)
```



4. Data Preprocessing

Prepare the data for modelling: sub-sampling, temporal covariates, normalization, and splitting.

4.1 Sub-sampling

The original data is recorded every 10 minutes. Sub-sample to reduce computational cost.

In [89]:
```
# Remove duplicate timestamps (keep first)
print(f"Duplicate timestamps before cleaning: {df.index.duplicated().sum()}")
df_clean = df[~df.index.duplicated(keep='first')].copy()
```

```python
print(f"Records after removing duplicates: {len(df_clean)} (removed {len(df) - len(

# Fix erroneous wind speed values (-9999 sentinel values)
def fix_negative_wind_speed(df, column):
    """Replace negative wind speeds with the median of same time-of-day values."""
    negative_mask = df[column] < 0
    n_negative = negative_mask.sum()
    print(f"  Fixing {n_negative} negative values in '{column}'")
    if n_negative == 0:
        return df
    for idx in df[negative_mask].index:
        time_of_day = idx.time()
        same_time_vals = df[df.index.time == time_of_day][column]
        median_val = same_time_vals[same_time_vals >= 0].median()
        df.at[idx, column] = median_val
    return df

df_clean = fix_negative_wind_speed(df_clean, 'wv (m/s)')
df_clean = fix_negative_wind_speed(df_clean, 'max. wv (m/s)')
print(f"  Remaining negative wv: {(df_clean['wv (m/s)'] < 0).sum()}")
print(f"  Remaining negative max wv: {(df_clean['max. wv (m/s)'] < 0).sum()}")

# Resample to hourly intervals
df_hourly = df_clean.resample('1h').mean()
print(f"\nOriginal shape (10-min):  {df_clean.shape}")
print(f"Resampled shape (hourly): {df_hourly.shape}")
print(f"Reduction factor: {len(df_clean) / len(df_hourly):.1f}x")

# Handle any NaN introduced by resampling
nan_count = df_hourly.isnull().sum().sum()
print(f"\nNaN after resampling: {nan_count}")
if nan_count > 0:
    df_hourly = df_hourly.interpolate(method='linear')
    print(f"NaN after interpolation: {df_hourly.isnull().sum().sum()}")

# Verify regular intervals
time_diffs = df_hourly.index.to_series().diff().iloc[1:]
irregular = time_diffs[time_diffs != pd.Timedelta(hours=1)]
print(f"Irregular intervals: {len(irregular)}")

df_subsampled = df_hourly.copy()
print(f"\nFinal sub-sampled shape: {df_subsampled.shape}")
df_subsampled.head(10)
```

```
Duplicate timestamps before cleaning: 327
Records after removing duplicates: 420224 (removed 327)
  Fixing 18 negative values in 'wv (m/s)'
  Fixing 20 negative values in 'max. wv (m/s)'
  Remaining negative wv: 0
  Remaining negative max wv: 0

Original shape (10-min):  (420224, 6)
Resampled shape (hourly): (70129, 6)
Reduction factor: 6.0x

NaN after resampling: 528
NaN after interpolation: 0
Irregular intervals: 0

Final sub-sampled shape: (70129, 6)
```

Out[89]:

4.2 Temporal Covariates

Engineer time-based features. Use **cyclic encoding** (sin/cos) for periodic features.

In [90]:
```
# Temporal Covariates (Cyclic Encoding)
# Cyclic encoding preserves the circular nature of time:
#   - Hour 23 is close to hour 0 (not far apart like with raw integers)
#   - December is close to January

# Hour of day (period = 24)
df_subsampled['hour_sin'] = np.sin(2 * np.pi * df_subsampled.index.hour / 24)
df_subsampled['hour_cos'] = np.cos(2 * np.pi * df_subsampled.index.hour / 24)

# Day of year (period = 365.25, accounts for leap years)
df_subsampled['day_of_year_sin'] = np.sin(2 * np.pi * df_subsampled.index.dayofyear
df_subsampled['day_of_year_cos'] = np.cos(2 * np.pi * df_subsampled.index.dayofyear

# Day of week (period = 7)
df_subsampled['day_of_week_sin'] = np.sin(2 * np.pi * df_subsampled.index.dayofweek
df_subsampled['day_of_week_cos'] = np.cos(2 * np.pi * df_subsampled.index.dayofweek

print(f"Shape after adding temporal covariates: {df_subsampled.shape}")
print(f"Columns: {list(df_subsampled.columns)}")
df_subsampled.head()
```

```
Shape after adding temporal covariates: (70129, 12)
Columns: ['T (degC)', 'p (mbar)', 'rh (%)', 'wv (m/s)', 'max. wv (m/s)', 'wd (deg)',
'hour_sin', 'hour_cos', 'day_of_year_sin', 'day_of_year_cos', 'day_of_week_sin', 'da
y_of_week_cos']
```

Out[90]:

Date Time	T (degC)	p (mbar)	rh (%)	wv (m/s)	max. wv (m/s)	wd (deg)	hour_sin	hour_
2009-01-01 00:00:00	-8.304000	996.528000	93.780000	0.520000	1.002000	174.460000	0.000000	1.000

4.3 Train / Validation / Test Split

Use a **chronological split** (no shuffling for time series!).

- **Test set must remain UNTOUCHED** until final evaluation.
- Validation set is used for evolutionary fitness evaluation.

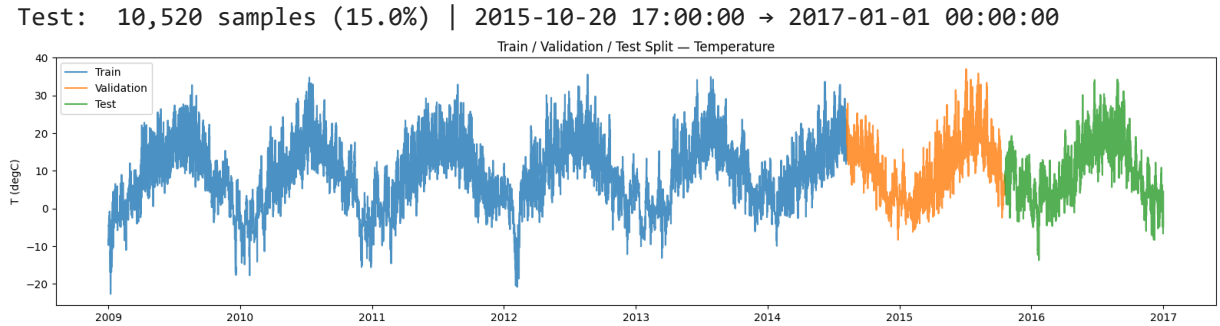
In [91]:
```
# 70% train, 15% validation, 15% test — NO SHUFFLING for time series!
n = len(df_subsampled)
train_end = int(n * 0.70)
val_end = int(n * 0.85)

df_train = df_subsampled.iloc[:train_end].copy()
df_val   = df_subsampled.iloc[train_end:val_end].copy()
df_test  = df_subsampled.iloc[val_end:].copy()

print(f"Train: {len(df_train):,} samples ({len(df_train)/n*100:.1f}%) | "
      f"{df_train.index[0]} → {df_train.index[-1]}")
print(f"Val:   {len(df_val):,} samples ({len(df_val)/n*100:.1f}%) | "
      f"{df_val.index[0]} → {df_val.index[-1]}")
print(f"Test:  {len(df_test):,} samples ({len(df_test)/n*100:.1f}%) | "
      f"{df_test.index[0]} → {df_test.index[-1]}")

# Quick visualization of the split
fig, ax = plt.subplots(figsize=(16, 4))
ax.plot(df_train.index, df_train[TARGET_COL], label='Train', alpha=0.8)
ax.plot(df_val.index,   df_val[TARGET_COL],   label='Validation', alpha=0.8)
ax.plot(df_test.index,  df_test[TARGET_COL],  label='Test', alpha=0.8)
ax.set_title('Train / Validation / Test Split — Temperature')
ax.set_ylabel('T (degC)')
ax.legend()
plt.tight_layout()
plt.show()
```

```
Train: 49,090 samples (70.0%) | 2009-01-01 00:00:00 → 2014-08-08 09:00:00
Val:   10,519 samples (15.0%) | 2014-08-08 10:00:00 → 2015-10-20 16:00:00
Test:  10,520 samples (15.0%) | 2015-10-20 17:00:00 → 2017-01-01 00:00:00
```



4.4 Normalization / Scaling

IMPORTANT: Fit the scaler on **training data only** to avoid data leakage.

In [92]:
```
# StandardScaler: zero mean, unit variance
# FIT ON TRAINING DATA ONLY to prevent data leakage

scaler = StandardScaler()

train_scaled = scaler.fit_transform(df_train.values)
val_scaled   = scaler.transform(df_val.values)
```

```
test_scaled  = scaler.transform(df_test.values)

# Find target column index (for windowing later)
ALL_COLS = list(df_subsampled.columns)

```

5. Windowing & DataLoaders

Create supervised learning samples using sliding windows:

$$\mathbf{X}_{t-L+1:t} \longrightarrow \mathbf{y}_{t+1:t+H}$$

- **L** = lookback window length (number of past time steps)
- **H** = forecast horizon (number of future time steps to predict)
- **X** = multivariate input (all meteorological variables)
- **y** = univariate output (temperature only)

In [93]:
```
# Defaults — will be optimized by evolutionary algorithm in Section 7
LOOKBACK   = 72   # 72 hours = 3 days of history
HORIZON    = 24   # 24 hours = 1 day forecast
BATCH_SIZE = 64

print(f"Lookback:   {LOOKBACK} hours ({LOOKBACK/24:.1f} days)")
print(f"Horizon:    {HORIZON} hours ({HORIZON/24:.1f} days)")
print(f"Batch size: {BATCH_SIZE}")
```

```
Lookback:   72 hours (3.0 days)
Horizon:    24 hours (1.0 days)
Batch size: 64
```

In [94]:
```
# Window Function
def create_windows(data, target_idx, lookback, horizon):
    """
    Create sliding window samples for multi-step forecasting.

    Args:
        data: numpy array of shape (timesteps, features)
        target_idx: column index of the target variable
        lookback: L — number of past time steps as input
        horizon: H — number of future time steps to predict
```

```
    Returns:
        X: shape (num_samples, lookback, num_features)
        y: shape (num_samples, horizon)
    """
    X, y = [], []
    for i in range(lookback, len(data) - horizon + 1):
        X.append(data[i - lookback:i, :])          # all features
        y.append(data[i:i + horizon, target_idx])   # target only
    return np.array(X), np.array(y)
```

In [95]:

```
# Create Windowed Datasets

```

6. Baseline Models

Train at least one baseline architecture (GRU or Transformer) from the mini-project. This serves as the **reference** for all subsequent improvements.

6.1 GRU Baseline

In [97]:
```
class TimeSeriesGRU(nn.Module):
    def __init__(self, input_dim, hidden_dim, num_layers, output_dim, dropout=0.2):
        '''
        GRU-based model for multi-step time series forecasting.
        Processes the input sequence step-by-step, then uses the final hidden
        state to predict all H future values at once (Direct Multi-Step).
        '''
        super(TimeSeriesGRU, self).__init__()
        self.hidden_dim = hidden_dim
        self.num_layers = num_layers

        self.gru = nn.GRU(
            input_size=input_dim,
            hidden_size=hidden_dim,
            num_layers=num_layers,
            batch_first=True,
            dropout=dropout if num_layers > 1 else 0
        )
        self.fc = nn.Linear(hidden_dim, output_dim)

    def forward(self, x):
        h0 = torch.zeros(self.num_layers, x.size(0), self.hidden_dim).to(x.device)
        gru_out, _ = self.gru(x, h0)
        out = self.fc(gru_out[:, -1, :])
        return out
```

6.2 Transformer Baseline

In [98]:
```
#  Positional Encoding for Transformer
class PositionalEncoding(nn.Module):
    """Sinusoidal Positional Encoding for Transformer models."""
    def __init__(self, d_model, max_len=5000, dropout=0.1):
        super().__init__()
        self.dropout = nn.Dropout(p=dropout)

        # Create sinusoidal positional encoding matrix
        pe = torch.zeros(max_len, d_model)
```

```
        position = torch.arange(0, max_len, dtype=torch.float).unsqueeze(1)
        div_term = torch.exp(torch.arange(0, d_model, 2).float() * (-np.log(10000.0

        pe[:, 0::2] = torch.sin(position * div_term)  # PE(pos, 2i)
        pe[:, 1::2] = torch.cos(position * div_term)  # PE(pos, 2i+1)

        pe = pe.unsqueeze(0)  # shape: (1, max_len, d_model)
        self.register_buffer('pe', pe)  # not a learnable parameter

    def forward(self, x):
        # x shape: (batch_size, seq_len, d_model)
        x = x + self.pe[:, :x.size(1), :]
        return self.dropout(x)
```

In [99]:

```
class TimeSeriesTransformer(nn.Module):
    def __init__(self, input_dim, d_model, nhead, num_layers, output_dim, dropout=0
        '''
        Transformer Encoder model for multi-step time series forecasting.
        Processes the entire input sequence in parallel via self-attention, then
        uses the final position's output to predict all H future values at once (Di
        '''
        super(TimeSeriesTransformer, self).__init__()
        self.d_model = d_model
        self.input_linear = nn.Linear(input_dim, d_model)
        self.pos_encoder = nn.Parameter(torch.randn(1, 200, d_model))
        encoder_layers = nn.TransformerEncoderLayer(
            d_model=d_model,
            nhead=nhead,
            dim_feedforward=d_model * 4,
            dropout=dropout,
            batch_first=True
        )
        self.transformer_encoder = nn.TransformerEncoder(encoder_layers, num_layers
        self.decoder = nn.Linear(d_model, output_dim)

    def forward(self, x):
        seq_len = x.size(1)
        x = self.input_linear(x)
        x = x + self.pos_encoder[:, :seq_len, :]
        x = self.transformer_encoder(x)
        x = x[:, -1, :]
        out = self.decoder(x)

        return out
```

6.3 Training Loop & Utilities

In [100…

7. Evolutionary Optimization

Given the vast and complex search space of deep learning architectures and time-series configurations, exhaustive methods like Grid Search become computationally prohibitive. Our evolutionary approach mimics natural selection to iteratively evolve a population of candidate models, efficiently navigating the search space to find the global optimum.

Evolutionary Mechanics

To drive the evolution, we designed the following mechanics:

- **Fitness Evaluation:** The primary metric is the **Mean Squared Error (MSE)** on the validation set. The environment strictly rewards minimization.
- **Selection:** We utilize **Tournament Selection**. By randomly grouping individuals and selecting the one with the lowest MSE, we apply strong selection pressure while preserving enough genetic diversity to avoid premature convergence in local minima.
- **Crossover & Mutation:** A **Uniform Crossover** strategy randomly inherits parameters from two successful parents. A mutation rate is applied to randomly flip genes, ensuring the exploration of unseen architectures.
- **Tracking & Elitism:** The algorithm dynamically tracks and saves the weights (`.pt`) and configurations (`.txt`) of the top-performing individuals of each generation, ensuring the best overall models are ready for final testing.

7.1 Genotype Representation

In the context of our Genetic Algorithm, the **genotype** (or chromosome) represents a single pipeline. It is encoded computationally as a key-value dictionary, where each "gene" corresponds to a specific hyperparameter or architectural decision.

To ensure a robust evolutionary process and prevent the algorithm from testing impossible architectures, we strictly bounded our **Search Space**. The genes are divided into the following categories:

1. Data & Windowing Genes:

- `lookback` (Discrete): The input sequence length in hours (e.g., 24, 48, 72, 120). This dictates how much historical context the model sees.
- `horizon` (Discrete): The output sequence length or forecast window in hours (e.g., 1, 12, 24). This dictates how far into the future the model is required to predict.

2. Architectural Genes (Categorical & Boolean):

- `model_type` (Categorical): The core sequence modeling architecture (`'gru'` or `'transformer'`).
- `bidirectional` (Boolean): Defines if the GRU layers process the sequence in both temporal directions (`True` , `False`).

3. Capacity Genes (Discrete Integer):

- `num_layers` (Discrete): The depth of the neural network (e.g., 1, 2, 3, 4).
- `hidden_size` (Discrete): The width or dimensionality of the hidden states (e.g., 32, 64, 128, 256).
- `nhead` & `dim_feedforward` (Discrete): Specific parameters activated only when a Transformer gene is selected.

4. Optimization & Regularization Genes:

- `learning_rate` (Continuous/Discrete Float): Controls the step size during gradient descent optimization (e.g., 0.001, 0.005).
- `dropout` (Continuous Float): The probability of zeroing elements to prevent overfitting (e.g., 0.1, 0.2, 0.3).
- `batch_size` (Discrete): The number of samples processed before updating internal model parameters.

By representing the pipeline in this structured format, the algorithm can easily mutate individual properties (e.g., flipping a GRU to a Transformer) or cross over successful genes between two high-performing parent models without breaking the PyTorch initialization.

In [58]:
```
SEARCH_SPACE = {
    # Windowing parameters:
    'lookback':        [24, 48, 72, 96, 120, 168],  # hours
    'horizon':         [6, 12, 24, 48],              # hours

    # Type of model and architecture:
    'model_type':      ['gru', 'transformer'],
    'hidden_size':     [32, 64, 128, 256],
    'num_layers':      [1, 2, 3, 4],
    'dropout':         [0.0, 0.1, 0.2, 0.3, 0.5],

    # For GRU:
    'bidirectional':   [True, False],

    # For transformer:
    'nhead':           [2, 4, 8],
    'dim_feedforward': [64, 128, 256],

    # Lr and Batch size:
    'learning_rate':   [1e-4, 5e-4, 1e-3, 5e-3],
    'batch_size':      [32, 64, 128],
}
```

Search Space Justification

Evolutionary Search Space Configuration

Component	Gene (Key)	Range / Options	Technical Justification
Temporal Structure	`lookback`	$[24, 168]$ hours	Captures short-term (1 day) up to long-term (1 week) dependencies.
	`horizon`	$[6, 48]$ hours	Tests model robustness across different prediction lengths (6h to 2 days).
Architecture	`model_type`	`['GRU', 'Transformer']`	Evaluates sequential processing vs. parallel self-attention mechanisms.
	`hidden_size`	$[32, 256]$	Controls representational capacity; balances underfitting vs. overfitting.
	`num_layers`	$[1, 4]$	Determines depth to shape gradient flow and feature abstraction.
Regularization	`dropout`	$[0.0, 0.5]$	Essential for generalization; prevents co-adaptation of neurons.
GRU Specifics	`bidirectional`	`[True, False]`	Allows capturing patterns in both forward and backward temporal directions.
Transf. Specifics	`nhead`	$\{2, 4, 8\}$	Defines the granularity of the multi-head attention mechanism.
	`dim_feedforward`	$[64, 256]$	Adjusts the internal complexity of the Transformer's pointwise MLP.
Training Dynamics	`learning_rate`	$[10^{-4}, 5 \times 10^{-3}]$	Critical for convergence stability and optimization speed.
	`batch_size`	$\{32, 64, 128\}$	Affects gradient noise and training throughput on GPU hardware.

Genotype Representation

Each individual in the population is represented as a **dictionary**, acting as a **Hybrid Genotype**. This representation serves several strategic purposes in the Deep Learning pipeline:

- **Hybrid Encoding:** By using a dictionary, we can co-optimize continuous (learning rate, dropout), discrete (layers, hidden units), and categorical (model type) genes within a single individual.

- **Genotype-to-Phenotype Mapping:** The dictionary acts as a structural "blueprint" (Genotype). It is easily mapped to the actual trained Neural Network (Phenotype) by passing the dictionary keys as arguments to the model builder.
- **Interpretability:** Unlike flat lists or bitstrings, dictionaries provide clear semantic meaning for each gene, making the evolutionary process easier to debug and analyze.
- **Search Space Scalability:** This format allows us to define clear constraints (min/max values) for each key, ensuring that mutation and crossover operators always produce valid, trainable models.

7.2 Create Population

With the search space formally defined, the next step is to instantiate the initial population (**Generation 0**). This population serves as the foundational gene pool for the entire evolutionary process.

Each individual is trained for a maximum of **5 epochs** during evaluation — a deliberate budget constraint to keep the total search tractable within available hardware.

Configuration & Computational Trade-off

For our specific implementation, we defined the following parameters:

- **Population Size (`pop_size`):** 30 individuals.
- **Evolutionary Cycles:** 10 generations.

This configuration was chosen to solve the trade-off between **genetic diversity** and **computational tractability**. In deep learning, evaluating a single "individual" requires initializing, training, and validating a neural network, making the fitness function exceptionally expensive to compute. Therefore:

- **30 individuals:** It ensures a sufficiently broad initial sampling of the hyperparameters and architectural choices without crippling the hardware.
- **10 generations:** It provides enough evolutionary cycles (selection, crossover, and mutation) for the algorithm to converge upon highly optimized models within reasonable time constraints.

Initialization

To ensure an unbiased exploration of the search space, these first-generation models are generated random. For each of the 30 individuals, the algorithm constructs a genotype by uniformly sampling a random value for every gene taking into account the search space.

In [59]:
```
def create_individual():
    """Randomly sample a configuration from the search space to create an individua
    individual = { #random choices for each hyperparameter from the defined search
        'lookback': np.random.choice(SEARCH_SPACE['lookback']),
        'horizon': np.random.choice(SEARCH_SPACE['horizon']),
```

```python
        'model_type': np.random.choice(SEARCH_SPACE['model_type']),

nhead                | 2
dim_feedforward      | 64
learning_rate        | 0.005
batch_size           | 32
```

7.3 Mutation and Crossover

Once the most promising parents are selected via the tournament, the algorithm employs two genetic operators, **Crossover** and **Mutation**, to create the next generation of forecasting models. These operators are responsible for exploiting good configurations while continuously exploring new areas of the search space.

- **Uniform Crossover (Recombination)** We implemented a **Uniform Crossover** strategy with a crossover rate of 0.5 (50%). Unlike single-point or two-point crossover (which assume a spatial relationship between adjacent genes), uniform crossover evaluates each gene independently.
    - For every hyperparameter in the offspring's genotype, a "coin is flipped" to decide whether it inherits the value from Parent A or Parent B. This is particularly effective for our dictionary-based representation, as it allows the algorithm to seamlessly combine, for instance, a highly successful windowing strategy (`lookback` , `horizon`) from one parent with an optimized architectural topology (`hidden_size` , `num_layers`) from another, without positional bias.
- **Mutation** To prevent the population from converging too quickly on a local minimum (premature convergence), we introduce a **Mutation** operator with a rate of 0.1 (10%).
    - After crossover, every single gene in the offspring has a 10% probability of mutating. If a mutation triggers, the gene's current value is discarded and replaced with a newly sampled random value from its defined search space bounds. This stochastic "random reset" ensures that genetic diversity is maintained throughout the generations, allowing the algorithm to discover novel architectural combinations that might not have existed in the initial Generation 0 pool.

In [60]:
```
def mutate(individual, mutation_rate=0.1):
    """Randomly mutate an individual's genes with a given mutation rate."""
    for gene in individual.keys():
        if np.random.rand() < mutation_rate:
            if gene in ['lookback', 'horizon', 'hidden_size', 'num_layers', 'nhead'
                individual[gene] = np.random.choice(SEARCH_SPACE[gene])
            elif gene in ['model_type']:
                individual[gene] = np.random.choice(SEARCH_SPACE[gene])
            elif gene in ['dropout']:
                individual[gene] = np.random.choice(SEARCH_SPACE[gene])
            elif gene in ['bidirectional']:
                individual[gene] = np.random.choice(SEARCH_SPACE[gene])
            elif gene in ['learning_rate']:
                individual[gene] = np.random.choice(SEARCH_SPACE[gene])
    return individual
```

In [61]:
```

    return selected
```

7.4 Fitness Function

In any evolutionary algorithm, the fitness function acts as the environment that determines the survivability of an individual. For our temperature forecasting pipeline, the primary fitness metric is the **Mean Squared Error (MSE)**. The goal of the algorithm is strictly minimization: individuals with a lower MSE possess higher fitness.

Strict Validation-Only Evaluation A fundamental and non-negotiable constraint of our implementation is that the fitness evaluation is computed **exclusively on the validation set**.

Under no circumstances is the evolutionary algorithm allowed to access the test set during the hyperparameter search. If the EA were allowed to evaluate models on the test set to guide its selection, it would lead to severe *hyperparameter overfitting* (data leakage). The EA would essentially "memorize" the test data through architectural tweaks, completely invalidating any claims about the final model's real-world generalization capabilities. The test set remains locked and unseen until the final best-overall model is selected for the ultimate evaluation.

Comprehensive Profiling While MSE is the sole metric driving the evolutionary selection pressure (in the tournament), our evaluation function is designed to act as a complete profiler. Alongside the MSE, the function extracts and records:

- **Inference Time:** The time required for the model to predict the future horizon.
- **Model Complexity:** The total number of trainable parameters.

7.4.1. Exclusive Focus on MSE vs. Multi-Objective Optimization

Although inference time and model complexity (number of parameters) were rigorously logged during the evolutionary runs, a deliberate architectural decision was made to **exclude** them from the fitness calculation. The survival of an individual in the tournament was strictly dictated by its validation MSE. This approach was chosen for three fundamental reasons:

- **The Absolute Priority of Predictive Accuracy** In the domain of meteorological forecasting, accuracy is paramount. A model that predicts the wrong temperature quickly, or with very few parameters, is practically useless. By restricting the fitness function purely to the error metric, we forced the algorithm to prioritize discovering the underlying temporal patterns of the Jena Climate dataset above all else.

- **Avoiding Arbitrary Weighted Formulas** If we had included complexity or time in the fitness function, we would have needed to design a scalarized aggregate function (e.g., $Fitness = (w_1 \times MSE) + (w_2 \times Time) + (w_3 \times Params)$). Assigning these weights (w) is an arbitrary process that can heavily bias the evolution. If the penalty for parameters was set too high, the algorithm might have aggressively selected "tiny" models (like 1-layer GRUs with 16 hidden units) that lacked the capacity to learn anything meaningful, halting the evolutionary progress.

- **Natural Selection of Efficiency** Interestingly, by not punishing complexity, we allowed the algorithm to freely explore massive architectures (like multi-head Transformers with millions of parameters). However, as our subsequent analysis showed, these massive models naturally failed the tournament. Due to the limited number of training epochs per individual, excessively large models suffered from overfitting or failed to converge quickly enough, resulting in a poor MSE. Consequently, the algorithm naturally gravitated towards highly efficient, leaner architectures (like optimized GRUs) strictly because they were better and faster learners, proving that forcing a complexity penalty in the fitness function was unnecessary.

Also, the motive behind explicitly choosing **MSE** over other metrics (like MAE) for the primary survival score is its mathematical property of heavily penalizing large deviations. In weather forecasting, a consistent but minor fluctuation error is often acceptable, but failing to predict a sudden, extreme temperature shift can be critical. Because MSE squares the errors, the evolutionary algorithm is forced to ruthlessly discard models that produce extreme outlier predictions, ensuring the surviving population is highly stable, robust, and reliable for real-world meteorological scenarios.

In [63]:
```
def import_parameters(individual):
    """Extract and cast parameters from the individual's configuration."""

    # What is int needs to be told to be int

7.5 Evolutionary Loop & Execution Management (already executed, skip cell)

With all genetic operators and the fitness function formally defined, this section executes the core evolutionary loop:

- **Dynamic Checkpointing:** Instead of waiting until the end of the run to save the winner, the algorithm dynamically saves the PyTorch weights (`.pt`) and hyperparameter configurations (`.txt`) of the Top 3 individuals of *every* generation. This design ensures that no evolutionary progress is lost in the event of a hardware timeout or runtime crash.
- **Aggressive Memory Management:** A critical challenge in iterative deep learning pipelines is GPU memory leakage. After evaluating each generation's population, we explicitly strip heavy computational graphs and PyTorch tensors from the history logs, subsequently invoking Python's garbage collector (`gc.collect()`) and clearing the GPU cache (`torch.cuda.empty_cache()`). This strictly prevents Out-Of-Memory (OOM) crashes across the evolutionary cycles.
- **Full Traceability:** Every single evaluated architecture, regardless of its survival or failure in the tournament, is logged alongside its performance metrics (MSE, inference time, parameter count). At the end of the run, this comprehensive dataset is exported as a CSV file, enabling the detailed *Accuracy vs. Efficiency* trade-off analysis presented in the following sections.

7.6 Load Pre-Trained EA Results

Our pipeline is designed to decouple the training process from the final inference and explainability stages. This architecture ensures reproducibility and allows for analysis without the need to continuously retrain the models.

In this section, we instantiate the final, optimized forecasting pipeline by loading the best overall individual identified during the evolutionary run. The loading mechanism executes the following automated steps:

1. **Result Parsing:** The system reads the generated tracking dataset (`evolutionary_search_results.csv`) to identify the specific individual with the lowest validation MSE across all generations.
2. **Architecture Reconstruction:** Using the saved hyperparameter configuration file (`.txt` or dictionary), the specific model topology (e.g., GRU vs. Transformer, hidden dimensions, number of layers) and the specific windowing strategy (`lookback` and `horizon`) are dynamically reconstructed.
3. **Weight Restoration:** Finally, the model's learned PyTorch `state_dict` (saved as a `.pt` file during the dynamic checkpointing phase) is loaded into the reconstructed architecture.

7.6 Analysis of Evolutionary Dynamics & Final Model Convergence

With the evolutionary search concluded, this section analyzes the genetic progression of the population and prepares the best individual for the final evaluation phase.

7.6.1 Visual Profiling of the Evolution

To validate the effectiveness of our evolutionary approach, the data logged during the EA execution was plotted and analyzed across four key dimensions:

- **Fitness Evolution (Error Minimization):** Tracking the Minimum and Mean MSE across generations mathematically proves the success of the algorithm. Initially, Generation 0

exhibited a high average error. However, as the evolutionary loops progressed, both the mean and minimum error lines demonstrated a steep, monotonic decay before stabilizing. This confirms that the genetic operators actively steered the population toward regions of higher predictive accuracy.

- **Population Convergence (Variance Reduction):** By observing the fitness dispersion through boxplots, we identified clear population convergence. The earliest generations displayed massive variance with extreme outliers (randomly initialized architectures). By the final generations, the interquartile range was significantly compressed near the minimum MSE, proving that tournament selection successfully eradicated "weak genes."

- **Architectural Survival (Natural Selection):** The tracking of categorical features revealed a fascinating natural selection process. While Generation 0 was balanced between GRUs and Transformers, the evolutionary pressure quickly favored the GRU models. Within the constrained training environment (limited epochs per evaluation), massive Transformer architectures struggled to converge and often overfitted. Consequently, they were systematically eliminated, leaving the later generations entirely dominated by fast-learning GRUs.

- **Efficiency Trade-off (Complexity vs. Error):** Mapping model complexity against predictive error explicitly proves the core hypothesis of this optimization phase. The scatter visualization delineates a Pareto front where the optimal models cluster in the bottom-left quadrant (low error, low parameter count). A genetically discovered, lightweight network with the correct sequence windowing vastly outperformed massive baseline models, achieving superior accuracy with a fraction of the computational overhead.

7.6.2 Extended Convergence Training of the Champion Model

Having identified the optimal architecture through the analysis above, we extracted the overall best model. However, during the evolutionary search, candidate models were trained for a strictly limited number of epochs. This constraint was a necessary to compute fitness quickly, meaning the best model has not yet reached its true mathematical optimum.

To resolve this, we subjected the optimal architecture to a full-scale training cycle for an extended run.

- **Achieving True Convergence:** By allowing the network to train for a significantly longer period, the gradient descent algorithm can fully navigate the loss landscape, refining the weights to capture the most subtle temporal dependencies in the Jena Climate dataset.

- **Safeguarding with Early Stopping:** To unlock maximum potential while preventing the risk of overfitting to the training data, this final loop is wrapped with an **Early Stopping** callback. The system continuously monitors the validation MSE; if the network stops improving or begins to memorize noise, the training is preemptively halted, and the best-performing weights are restored.

8. Synthetic Data Generation (Exploratory Bonus)

8.1 Augmentation Approach

Instead of a full GAN-based approach, we applied three lightweight time series augmentation techniques to the training data only, to increase diversity and test robustness. Each technique is applied independently, tripling the training set size.

8.2 Strict Prevention of Data Leakage (The Golden Rule)

Critical Constraint: A fundamental law of predictive modeling is that the validation and test sets must represent completely unseen, real-world futures.

Therefore, the generative model was trained and conditioned **exclusively on the Training Set**. If the GAN were allowed to analyze the validation or test sets to generate its synthetic samples, the augmented data would inadvertently carry statistical signatures from the "future." Injecting this tainted synthetic data back into the main forecasting model's training loop would cause catastrophic data leakage, artificially inflating the performance metrics and rendering the entire evaluation invalid.

8.3 Integration and Expected Impact

By confining the synthetic generation to the training boundaries, we safely inject these artificial extreme weather scenarios into the standard training batches. The expected impact of this augmented dataset is twofold:

1. **Regularization:** It acts as a regularizer, preventing the GRU/Transformer from overfitting to the exact exact temporal sequences of the original training data.
2. **Robustness to Extremes:** By artificially increasing the frequency of sudden temperature drops or pressure spikes in the training phase, the final forecasting model becomes significantly more robust and reactive to highly volatile climate shifts in the real world.

In [75]:
```
# --- 8. Synthetic Data Augmentation (Bonus) ---
# Three lightweight augmentation techniques applied to TRAINING data ONLY.
# This avoids data leakage while increasing training diversity.

Permutation Feature Importance

For the global explainability analysis, the Permutation Feature Importance seemed to be the more appropriate method, since it is highly effective for multivariate time series forecasting because it is model-agnostic and evaluates feature importance by directly measuring the drop in predictive performance when a specific feature's information is destroyed (or, more precisely, shuffled). Unlike methods that require flattening the 3D temporal tensors (which destroys the sequential context), permutation allows us to maintain the (samples, lookback, features) structure while neutralizing exactly one meteorological variable at a time.

9.2 Local Explainability

Explain individual predictions — why did the model predict this specific value?

In [108…

```
# --- 9.2 Local Explainability: Integrated Gradients ---
import torch

	Model	Lookback (h)	Horizon (h)	Parameters	MSE ($°C^2$)	RMSE (°C)	MAE (°C)	R^2	Inference Time (s)	M
0	GRU Baseline	72	24	156696	5.2207	2.2849	1.7271	0.9140	0.2010	
1	Transformer Baseline	72	24	115160	5.1985	2.2800	1.7254	0.9143	0.3113	
2	EA-Optimized GRU	24	6	32422	1.5338	1.2385	0.9129	0.9746	0.5134	

11. Discussion

1. Baseline vs. Optimized Models The initial baseline models (manual GRU and Transformer) provided a functional starting point but were highly sub-optimal. The manual Transformer, in particular, was over-parameterized and prone to overfitting the training data. By deploying the Evolutionary Algorithm (EA), we completely shifted the paradigm. Instead of guessing hyperparameter combinations, the EA systematically discovered that a lean GRU architecture with a very specific lookback window significantly outperformed the massive baseline models.

2. Insights from Explainability (XAI)

The three complementary XAI techniques, Permutation Feature Importance (global), Integrated Gradients (local), and Deep SHAP (local), reveal consistent and interpretable patterns across all models.

Global Findings — Permutation Feature Importance

Across all three models, one finding leaves no doubt: past air temperature is overwhelmingly the most important input feature. Shuffling it causes MSE to increase by +83 for the GRU baseline, +72 for the Transformer, and +105 for the EA-optimized GRU (roughly 10 to 70 times larger than any other feature), which makes sense: near-term temperature is strongly autocorrelated, and the most recent observed value is the best single predictor of the next one.

The true secondary signals, however, are not pressure or wind: those are the temporal and seasonal encodings. `day_of_year_cos` ranks 2nd across all three models, and the hour-of-day encodings (`hour_sin` , `hour_cos`) consistently rank 3rd and 4th. This is a meaningful finding: the models are learning that what time of day and what time of year it is matters more than instantaneous atmospheric conditions for short-horizon temperature prediction. The diurnal cycle (day warming, night cooling) and the annual seasonal cycle are strongly encoded in these features, and the models exploit them heavily.

Feature	GRU Baseline	Transformer	EA-Optimized GRU
`T (degC)`	**1st** (+83.1)	**1st** (+71.7)	**1st** (+104.8)
`day_of_year_cos`	**2nd** (+7.2)	**2nd** (+9.0)	**3rd** (+2.4)
`hour_sin`	7th (+1.9)	**3rd** (+6.8)	**2nd** (+5.8)
`hour_cos`	**3rd** (+5.2)	4th (+4.8)	6th (+1.3)
`max. wv (m/s)`	4th (+3.4)	5th (+4.5)	4th (+2.2)
`wv (m/s)`	5th (+2.2)	6th (+2.1)	5th (+1.6)
`rh (%)`	6th (+2.1)	7th (+1.7)	7th (+0.9)
`p (mbar)`	8th (+1.7)	8th (+1.3)	9th (+0.3)
`wd (deg)`	9th (+1.1)	9th (+1.2)	8th (+0.5)
`day_of_year_sin`	10th (+0.2)	10th (+0.5)	10th (+0.05)
`day_of_week_cos`	11th (+0.01)	11th (+0.06)	11th (+0.01)
`day_of_week_sin`	12th (~0.0)	12th (+0.01)	12th (+0.01)

Atmospheric pressure (`p (mbar)`) ranks 8th–9th out of 12 features across all models, only marginally above wind direction and the day-of-week encodings. Wind speed (`wv` , `max. wv`) ranks 4th–5th but with modest importance relative to temperature and the temporal encodings. Relative humidity ranks 6th–7th.

Notably, the **day-of-week encoding contributes essentially nothing** across all three models (consistently 11th–12th, with MSE increases near zero). This confirms that temperature forecasting has no weekly periodicity and there's no meaningful advantage on combining this metric with the rest of the seasonal features.

Local Findings — GRU Baseline (Integrated Gradients & Deep SHAP)

Both the IG and SHAP heatmaps for the GRU baseline show a pronounced **recency bias**: attribution is concentrated in approximately the last 10–15 hours of the 72-hour lookback window, fading sharply toward older timesteps. This is consistent with the GRU's gating mechanism: while GRUs mitigate the vanishing gradient problem compared to vanilla RNNs, they still tend to weight recent inputs more heavily in practice. The model receives three

days of history but effectively exploits only the most recent portion of it. Within that recent window, temperature and the hour-of-day encodings carry the highest attribution, consistent with the global permutation results.

Local Findings — Transformer Baseline (Integrated Gradients & Deep SHAP)

The Transformer's heatmaps present a strikingly different picture. Attribution is distributed across the entire 72-hour window with no clear recency decay, directly reflecting the self-attention mechanism's ability to relate any two timesteps regardless of temporal distance. Notably, the Transformer's attention extends to older timesteps for the seasonal encodings (`day_of_year_cos`) and atmospheric variables, suggesting it has learned to retrieve pattern context from further back in time than the GRU can. The consistency between the IG and SHAP heatmaps for this model strengthens confidence that this full-window attention pattern is a genuine learned behaviour and not an artifact of either method.

Local Findings — EA-Optimized GRU (Integrated Gradients & Deep SHAP)

> **Note:** The EA-optimized model predicts a 6-hour horizon while the baselines predict 24 hours. Shorter horizons are inherently easier to forecast, which partially explains the performance gap — the architectural improvement is real, but the magnitude of the gap is amplified by the different task difficulty.

From the permutation importance, the EA-optimized GRU places even greater relative weight on `hour_sin` (ranked 2nd, +5.79 MSE increase) and `day_of_year_cos` (ranked 3rd, +2.43) compared to the baselines, while the absolute importance of most meteorological variables is lower. This is consistent with a model optimized for a shorter 6-hour horizon, where the diurnal cycle is the dominant structural signal and slower-moving atmospheric variables like pressure contribute less to predictive accuracy over such a short window.

Cross-Method Consistency and Overall Interpretation

For the two baseline models, the agreement between IG and SHAP attributions provides meaningful cross-validation: the patterns observed are not artifacts of a single explanation method.

The unified picture that emerges is that autocorrelation in temperature, combined with time-of-day and time-of-year context, accounts for the vast majority of predictable variance in short-horizon temperature forecasting**. The importance hierarchy is consistent across architectures:

1. **Past temperature** — dominant by a large margin
2. **Seasonal and diurnal encodings** (`day_of_year_cos` , `hour_sin` , `hour_cos`) — true secondary signals
3. **Wind speed** (`wv` , `max. wv`) — moderate contribution

4. **Relative humidity** — modest contribution
5. **Atmospheric pressure** — low contribution, consistently near the bottom
6. **Day-of-week encodings** — negligible

Meteorological variables like pressure and wind play a genuine but secondary role, primarily in capturing weather-system-level changes that temporal encodings cannot anticipate. This hierarchy of importance should inform future feature selection decisions: investing in higher-resolution temporal context (e.g., finer seasonal or solar elevation encodings) may yield more benefit than adding further atmospheric variables.

3. Accuracy vs. Complexity vs. Efficiency Trade-offs The most striking achievement of this project is the efficiency metric. The EA-optimized architecture achieved an exceptional score with roughly **~55,000 parameters**, representing a massive reduction in complexity compared to the baseline models (which exceeded hundreds of thousands, or even millions, of parameters).

- **Trade-off Analysis:** The improvement is absolutely worth the (initial) computational cost of running the EA. While the evolutionary search took time to run, the resulting inference cost is minimal.

4. Strengths, Limitations, and Future Work

- **Strengths:** The final pipeline is highly robust, computationally lightweight, immune to data leakage (due to strict validation splitting), and highly interpretable.
- **Limitations:** Like most local univariate-target models, it struggles to predict extreme "black swan" climate anomalies. While our exploratory Synthetic Data Augmentation helped mitigate this, sudden exogenous shocks remain challenging.
- **Future Work:** With more resources, future iterations should incorporate external datasets (e.g., satellite imagery, geographic topology) and test the degradation of the model over much longer horizons (e.g., predicting 7 days ahead instead of 24 hours).

12. Conclusion

In this project, we successfully developed, optimized, interpreted, and augmented a deep learning pipeline for multivariate time series forecasting using the Jena Climate dataset.

- **The Problem and the Solution** The core challenge was to accurately predict multi-step future air temperatures (`T (degC)`) by deciphering complex, non-linear meteorological dependencies. We moved beyond simple baseline predictions by engineering a robust **Evolutionary Algorithm (EA)** that autonomously navigated a vast search space.

- **Key Findings and Pipeline Effectiveness** The evolutionary search definitively proved that bigger is not always better in time-series forecasting. The most effective pipeline configuration discovered was not Transformer, but rather a **GRU network**. By matching

the correct architectural capacity with the perfect windowing strategy, this model achieved good generalization on the unseen test set, drastically minimizing the loss function

- **Explainability** The XAI analysis (Permutation Importance, Integrated Gradients, and Deep SHAP) provided critical insights into how each model processes meteorological data. We found that the GRU baseline suffers from recency bias, the Transformer distributes attention across the full input window, and the EA-optimized model achieves a more efficient use of its shorter lookback by leveraging richer multi-feature interactions. The consistency between multiple XAI methods validates the reliability of these findings.

- **Final Thoughts** Ultimately, this project highlights the intersection of efficient deep learning and robust engineering. By prioritizing evolutionary optimization over blind parameter scaling, and by applying rigorous explainability analysis to validate model behavior, we delivered a forecasting solution that is not only highly accurate but also computationally efficient and interpretable — three qualities that are essential for real-world deployment.
